## 1 Laplace Transform

**Definition 1.1** (Laplace Transform). The **Laplace Transform** of a function  $f(t)$  (for  $t \geq 0$ ) is the function  $\tilde{f}(z)$  defined by

$$\tilde{f}(z) = \mathcal{L}\{f\}(z) = \int_0^{\infty} e^{-zt} f(t) dt \quad (1.1)$$

where  $z$  is complex.

**Proposition 1.2** (Asymptotic Behavior of Laplace Transform). *Suppose  $g$  is analytic in a region containing the positive real axis and is bounded on the positive real axis. Let the Taylor series for  $g$  centered at 0 be*

$$\sum_{n=0}^{\infty} a_n z^n \quad (1.2)$$

and let

$$\tilde{g}(z) = \int_0^{\infty} e^{-zt} g(t) dt. \quad (1.3)$$

Then

$$\tilde{g}(z) \sim \frac{a_0}{z} + \frac{a_1}{z^2} + \frac{2a_2}{z^3} + \cdots + \frac{n!a_n}{z^{n+1}} + \cdots \quad (1.4)$$

as  $z \rightarrow \infty$ ,  $\arg(z) = 0$ .

**Proposition 1.3.** Suppose  $g$  is infinitely differentiable on the positive real axis and that  $g$  and each of its derivatives are of exponential order. That is, there are constants  $A_n$  and  $B_n$  such that

$$|g^{(n)}(t)| \leq A_n e^{B_n t} \quad (1.5)$$

for  $t \geq 0$ . Let

$$\tilde{g}(z) = \int_0^\infty e^{-zt} g(t) dt. \quad (1.6)$$

Then

$$\tilde{g}(z) \sim \frac{g(0)}{z} + \frac{g'(0)}{z^2} + \frac{g''(0)}{z^3} + \cdots + \frac{g^{(n)}(0)}{z^{n+1}} + \cdots \quad (1.7)$$

as  $z \rightarrow \infty$ ,  $\arg(z) = 0$ .

**Theorem 1.4** (Convergence Theorem for Laplace Transform). Assume

$$f : (0, \infty) \rightarrow \mathbb{C} \quad (1.8)$$

is of exponential order and let

$$\tilde{f}(z) = \int_0^\infty e^{-zt} f(t) dt. \quad (1.9)$$

There exists a unique number  $\sigma$ ,  $-\infty \leq \sigma < \infty$  such that this integral converges if  $\operatorname{Re}(z) > \sigma$  and diverges if  $\operatorname{Re}(z) < \sigma$ . Furthermore if  $\tilde{f}$  is analytic on the set

$$A = \{z \mid \operatorname{Re}(z) > \sigma\} \quad (1.10)$$

and we have

$$\frac{d}{dz} \tilde{f}(z) = - \int_0^\infty t e^{-zt} f(t) dt \quad (1.11)$$

for  $\operatorname{Re}(z) > \sigma$ . The number  $\sigma$  is called the “**Abcissa of Convergence**” and if we define the number  $\rho$  by

$$\rho = \inf\{B \in \mathbb{R} \mid \text{there exists an } A > 0 \text{ such that } |f(t)| \leq A e^{Bt}\} \quad (1.12)$$

then  $\sigma \leq \rho$ .

**Theorem 1.5** (Laplace Transforms). Suppose that the functions  $f$  and  $h$  are continuous and that  $\tilde{f}(z) = \tilde{h}(z)$  for  $\operatorname{Re}(z) > \gamma_0$  for some  $\gamma_0$ . Then  $f(t) = h(t)$  for all  $t \in (0, \infty)$ .

**Proposition 1.6.** Let  $f(t)$  be continuous on  $(0, \infty)$  and piecewise  $C^1$ . Then for  $\operatorname{Re}(z) > \rho$

$$\widetilde{\left(\frac{df}{dt}\right)}(z) = z\tilde{f}(z) - f(0). \quad (1.13)$$

**Proposition 1.7.** Let

$$g(t) = \int_0^t f(\tau) d\tau \quad (1.14)$$

Then for  $\operatorname{Re}(z) > \max[0, \rho(f)]$ ,

$$\tilde{g}(z) = \frac{\tilde{f}(z)}{z}. \quad (1.15)$$

**Theorem 1.8** (First Shifting Theorem). Fix  $a \in \mathbb{C}$  and let  $g(t) = e^{-at} f(t)$ . Then for  $\operatorname{Re}(z) > \sigma(f) - \operatorname{Re}(a)$ , we have

$$\tilde{g}(z) = \tilde{f}(z + a). \quad (1.16)$$

**Theorem 1.9** (Second Shifting Theorem). *Let  $H(t) = 0$  if  $t < 0$  and  $H(t) = 1$  if  $t \geq 0$  be the **Step Function** or **Heaviside Step Function**. Let  $a \geq 0$  and let  $g(t) = f(t - a)H(t - a)$ ; that is,  $g(t) = 0$  if  $t < a$  while  $g(t) = f(t - a)$  if  $t \geq a$ . Then for  $\text{Re}(z) > 0$  we have*

$$\tilde{g}(z) = e^{-az} \tilde{f}(z). \quad (1.17)$$

**Definition 1.10** (Convolution). The “**Convolution**” of two functions  $f(t)$  and  $g(t)$  is defined for  $t \geq 0$  by

$$(f * g)(t) = \int_0^\infty f(t - \tau)g(\tau)d\tau \quad (1.18)$$

where we set  $f(t) = 0$  if  $t < 0$ .

**Theorem 1.11** (Convolution Theorem). *The equalities*

$$(f * g)(t) = (g * f)(t) \quad (1.19)$$

*whenever  $\text{Re}(z) > \max[\rho(f), \rho(g)]$ .*

### 1.1 Table of Properties of the Laplace Transform

Let  $u(t)$  be the Heaviside step function.

$$u(t) = \int_{-\infty}^t \delta(\tau)d\tau \quad (1.20)$$

where  $\delta$  is the delta function we all know and love.

Linearity	$af(t) + bg(t)$	$a\tilde{f}(z) + b\tilde{g}(z)$
Frequency Differentiation	$tf(t)$	$-\tilde{f}'(z)$
Frequency Differentiation	$t^n f(t)$	$(-1)^n \tilde{f}^{(n)}(z)$
Differentiation	$f'(t)$	$z\tilde{f}(z) - f(0)$
Differentiation	$f''(t)$	$z^2\tilde{f}(z) - zf(0) - f'(0)$
Differentiation	$f^{(n)}(t)$	$z^n\tilde{f}(z) - z^{n-1}f(0) - \dots - f^{(n-1)}(0)$
Frequency Integration	$f(t)/t$	$\int_z^\infty \tilde{f}(\omega)d\omega$
Integration	$\int_0^t f(\tau)d\tau = (u * f)(t)$	$\tilde{f}(z)/z$
Scaling	$f(at)$	$\tilde{f}(z/a)/ a $
Frequency Shifting	$e^{at}f(t)$	$\tilde{f}(z - a)$
Time shifting	$f(t - a)u(t - a)$	$e^{-az}\tilde{f}(z)$
Convolution	$(f * g)(t)$	$\tilde{f}(z)\tilde{g}(z)$
Periodic Function	$f(t)$	$(\int_0^T e^{-zt}f(t)dt)/(1 - e^{-Tz})$

### 1.2 List of Properties of the Laplace Transform

**Definition.** The Laplace transform of  $f(t)$  is given by:

$$\tilde{f}(z) = \int_0^\infty e^{-zt}f(t)dt. \quad (1.21)$$

It is such that:

1.  $\tilde{g}(z) = -\frac{d}{dz}\tilde{f}(z)$  where  $g(t) = tf(t)$ .
2.  $\mathcal{L}\{af + bg\} = a\tilde{f} + b\tilde{g}$
3.  $\widetilde{\left(\frac{df}{dt}\right)}(z) = z\tilde{f}(z) - f(0)$ .

## 2 Gamma Function

So for  $n$  a positive integer, we have

$$\Gamma(n) = (n-1)! \quad (2.1)$$

### 2.1 List of Properties of the Gamma Function

Remember that it is defined as

$$\Gamma(z) = \int_0^\infty t^{z-1} e^{-t} dt. \quad (2.2)$$

or equivalently as an infinite product

$$\Gamma(z) = \frac{1}{ze^{\gamma z} \left[ \prod_{n=1}^\infty \left(1 + \frac{z}{n}\right) e^{-z/n} \right]} \quad (2.3)$$

where

$$\begin{aligned} \gamma &= \lim_{n \rightarrow \infty} \left( 1 + \frac{1}{2} + \cdots + \frac{1}{n} - \ln(n) \right) \\ &\approx 0.577215664901532860606512090082 \end{aligned} \quad (2.4)$$

It has the following properties:

1.  $\Gamma$  is meromorphic with simple poles at  $0, -1, -2, \dots$
2.  $\Gamma(z+1) = z\Gamma(z)$  for  $z \neq 0, -1, -2, \dots$
3.  $\Gamma(n+1) = n!$  for  $n = 0, 1, \dots$
4.  $\Gamma(z)\Gamma(1-z) = \frac{\pi}{\sin(\pi z)}$
5.  $\Gamma(z) \neq 0$  for all  $z$
6.  $\Gamma\left(\frac{1}{2}\right) = \sqrt{\pi}$ ,  $\Gamma\left(n + \frac{1}{2}\right) = \frac{1 \cdot 3 \cdot (\dots) \cdot (2n-1)}{2n} \sqrt{\pi}$
7.  $\Gamma(z) = \frac{1}{z} \prod_{n=1}^\infty \left[ \left(1 + \frac{1}{n}\right)^z \left(1 + \frac{z}{n}\right)^{-1} \right]$
8.  $\Gamma(z) = \lim_{n \rightarrow \infty} \frac{n! n^z}{z(z+1)(\dots)(z+n)}$
9.  $\Gamma(z)\Gamma\left(z + \frac{1}{n}\right)(\dots)\Gamma\left(z + \frac{n-1}{n}\right) = (2\pi)^{(n-1)/2} n^{(1/2)-nz} \Gamma(nz)$
10.  $2^{2z-1} \Gamma(z) \Gamma\left(z + \frac{1}{2}\right) = \sqrt{\pi} \Gamma(2z)$
11. The residue of  $\Gamma(z)$  at  $z = -m$  is equals  $(-1)^m/m!$
12. (Euler's Integral)  $\Gamma(z) = \int_0^\infty t^{z-1} e^{-t} dt$  for  $\operatorname{Re}(z) > 0$ . The convergence is uniform and absolute for  $-\pi/2 + \delta \leq \arg(z) \leq \pi/2 + \delta$  ( $\delta > 0$ ) and for  $\varepsilon \leq |z| \leq R$  where  $0 < \varepsilon < R$ .
13.  $\frac{\Gamma'(z)}{\Gamma(z)} = -\gamma - \frac{1}{z} + \sum_{n=1}^\infty \left( \frac{1}{n} - \frac{1}{z+n} \right) = \int_0^\infty \left( \frac{e^{-t}}{t} - \frac{e^{-zt}}{1-e^{-t}} \right) dt.$

14.  $\pi^{-z/2} \Gamma\left(\frac{z}{2}\right) \zeta(z) = \pi^{-\frac{1-z}{2}} \Gamma\left(\frac{1-z}{2}\right) \zeta(1-z)$ . (Where  $\zeta(s)$  is the Riemann zeta function)

15.  $\zeta(z) \Gamma(z) = \int_0^\infty \frac{u^{z-1}}{e^u - 1} du$  which holds for  $\text{Re}(z) > 1$ .

### 3 Zeta Function

The definition for the Riemann zeta function is

$$\zeta(s) = \sum_{n=1}^{\infty} \frac{1}{n^s} = \frac{1}{1^s} + \frac{1}{2^s} + \frac{1}{3^s} + \cdots \quad (3.1)$$

It is holomorphic everywhere except for a simple pole at  $s = 1$  with residue 1.

For any positive even integer  $2n$ , we have

$$\zeta(2n) = (-1)^{n+1} \frac{B_{2n} (2\pi)^{2n}}{2(2n)!} \quad (3.2)$$

where  $B_{2n}$  is a Bernoulli number, and for negative integers we have

$$\zeta(-n) = \frac{-B_{n+1}}{n+1} \quad (3.3)$$

for  $n \geq 1$ .

Let

$$f(x) = \frac{x}{e^x - 1} \quad (3.4)$$

then the Bernoulli numbers may be found from

$$B_n = \lim_{x \rightarrow 0} \frac{d^n}{dx^n} \frac{x}{(e^x - 1)}. \quad (3.5)$$

Observe that for  $n = 1$

$$f'(x) = \left( \frac{1}{e^x - 1} \right) \left( 1 - \frac{f(x)}{e^x - 1} \right) \quad (3.6)$$

and now observe that

$$\frac{d}{dx} \left( \frac{1}{e^x - 1} \right) = -e^x \left( \frac{1}{e^x - 1} \right)^2 \quad (3.7)$$

and we can use the product rule to find all of our favorite Bernoulli numbers.

We have a table of the first few Bernoulli numbers:

$n$	$B_n$
0	1
1	-1/2
2	1/6
4	-1/30
6	1/42
8	-1/30
10	5/66 $\approx$ 0.07575757576
12	-691/2730 $\approx$ -0.25311355311
14	7/6
16	-3617/510 $\approx$ -7.09125686275
18	43867/798 $\approx$ 54.9711779448

The zeta function satisfies the functional equation

$$\zeta(s) = 2^s \pi^{s-1} \sin\left(\frac{\pi s}{2}\right) \Gamma(1-s) \zeta(1-s), \quad (3.8)$$

valid for all  $s \in \mathbb{C}$ . An equivalent relationship may be expressed as a sum

$$\zeta(s)(1 - 2^{1-s}) = \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n^s}. \quad (3.9)$$

### 3.1 Mellin Transform

The Mellin transform of a function  $f(x)$  is defined as

$$\int_0^{\infty} f(x) x^{s-1} dx, \quad (3.10)$$

when defined. We can relate the zeta function to one million and one things this way, we have

$$\Gamma(s)\zeta(s) = \int_0^{\infty} \frac{x^{s-1}}{\exp(x) - 1} dx, \quad (3.11)$$

where  $\Gamma$  is our favorite gamma function, and

$$2 \sin(\pi s) \Gamma(s) \zeta(s) = i \oint_C \frac{(-x)^{s-1}}{\exp(x) - 1} dx \quad (3.12)$$

for all  $s$  where the contour  $C$  begins and ends at  $+\infty$  and circles the origin once.

### 3.2 Laurent Series

Since the zeta function has a single simple pole at  $s = 1$  we can expand it around the singular point. The series is

$$\zeta(s) = \frac{1}{s-1} + \sum_{n=0}^{\infty} \frac{(-1)^n}{n!} \gamma_n (s-1)^n. \quad (3.13)$$

where  $\gamma_n$  are the Stieltjes constants, defined by the limit

$$\gamma_n = \lim_{m \rightarrow \infty} \left( \left( \sum_{k=1}^m \frac{(\log k)^n}{k} \right) - \frac{(\log m)^{n+1}}{n+1} \right). \quad (3.14)$$

where the constant  $n = 0$  term in the Laurent series is just  $\gamma_0$  the Euler-Mascheroni constant.
